Abstract

The concept of magnitude is introduced by Leinster [2] and it is defined for enriched categories of finite objects, for example, generalized finite metric spaces such as finite graphs. Then, Leinster focuses on the magnitude of graphs in [1] using his idea of magnitude of a metric space, which is one of a family of cardinality-like invariants extending across mathematics; it is a cousin to Euler characteristic and geometric measure. Among its cardinality-like properties are multiplicativity with respect to cartesian product and an inclusion-exclusion formula for the magnitude of a union under mild hypotheses. Formally, the magnitude of a graph is both a rational function over \mathbb{Q} and a power series over \mathbb{Z} .

Richard and Simon introduced a bigraded homology theory for graphs which has the magnitude as its graded Euler characteristic and showed how properties of magnitude proved by Leinster categorify to properties such as a Kunneth Theorem and a Mayer-Vietoris Theorem.

Here, we first review the definition of the magnitude of graphs, the magnitude homology of graphs, and their properties. Then we focus on the magnitude of enriched categories and discuss how the magnitude of graphs is introduced from that of enriched categories.

1 Introduction

In many fields of mathematics, there is a canonical measure of size. Sets have cardinality, vector spaces have dimension, and topological spaces have Euler characteristic. Many of these cardinality-like invariants arise from a single general definition. This general invariant is called magnitude.

The full definition of magnitude is framed in the very wide generality of enriched categories of finite objects, as introduced by Leinster [2]. First, we take one of examples of enriched categories, graphs, in Section 2.

Finite graphs are seen as generalized finite metric spaces (See Example 4.2.7(ii)), with distance between vertices measured as the length of a shortest path. Among their special properties is that distances are integers. As we shall see, this has the consequence that for a graph G , the magnitude $\#G$ is a rational function of q over \mathbb{Q} . (It can also be expressed as a power series in q over \mathbb{Z} .) We write it as $\#G = \#G(q)$ to avoid confusion with the usage of G for the number of vertices of G , while still evoking the analogy with cardinality. Among the cardinality-like properties of magnitude are that

$$\#(G \square H) = \#G \cdot \#H,$$

where \square denotes the cartesian product of graphs (defined Definition 2.2.6). For example, let $G = K_2 \square K_3$. Then we have

$$\# \begin{array}{c} \bullet \\ \diagup \quad \diagdown \\ \bullet \quad \bullet \\ \diagdown \quad \diagup \\ \bullet \end{array} = \# \begin{array}{c} \bullet \\ | \\ \bullet \end{array} \cdot \# \begin{array}{c} \bullet \\ \diagup \quad \diagdown \\ \bullet \quad \bullet \end{array} \quad (\text{See Example 2.2.8}).$$

Also, for the disjoint union \sqcup of graphs, we have

$$\#(G \sqcup H) = \#G + \#H.$$

The trivial invariant number of vertices also satisfies these equations, and indeed, the number of vertices can be recovered from its magnitude as $\#G(0)$, but of course, magnitude is much more informative than that. For instance, the number of edges is $-\frac{1}{2} \frac{d}{dq} \#G(q) \Big|_{q=0}$ (See Corollary 2.2.11). However, there are graphs with the same magnitude that are easily distinguished by well-known graph invariants (See Example 2.2.8, easily distinguished by bipartiteness). In that sense, magnitude seems to capture

genuinely new aspects of a graph, at the same time as having uniquely good cardinality-like properties.

There is a certain property that we would like graph invariants to satisfy, the inclusion-exclusion formula;

$$\#(G \cup H) = \#G + \#H - \#(G \cap H).$$

For this we must impose some hypotheses. Indeed, Leinster shows that there is no nontrivial graph invariant that is fully cardinality-like in the sense of satisfying both multiplication and inclusion-exclusion formula without restriction (c.f. Lemma 2.3.3). However, the hypotheses we impose are mild enough to cover a wide range of examples, including trees, forests, wedge sums, and graphs containing a cycle of length at least 4. For example, let G be a graph shown below.

⊠ 1: A 3-cycle with edges attached to two distinct vertices

Then we can calculate the magnitude of G by decomposing it into $C_3 \cup C_2 \cap C_2$ as Example 2.3.14:

$$\#G = (\#C_3 + \#C_2 - \#C_1) + \#C_2 - \#C_1 = \#C_3 + 2\#C_2 - 2\#C_1.$$

Richard and Simon then categorify the magnitude of graphs by defining the magnitude homology of graphs in [3]. This is a bigraded homology theory $MH_{*,*}$. It is functorial with respect to maps of graphs that send vertices to vertices and preserve or contract edges, and its graded Euler characteristic recovers the magnitude:

$$\sum_{k,l \geq 0} (-1)^k \text{rank}(MH_{k,l}(G)) q^l = \#G \text{ in } \mathbb{Z}[[q]].$$

Being a bigraded abelian group rather than just a power series, the magnitude homology has a richer structure than the magnitude. For example, consider the cycle graph C_5 .

表 1: The ranks of $\text{MC}_{k,l}(C_5)$, the magnitude chain groups of the five-cycle graph.

		k											
		0	1	2	3	4	5	6	7	8	9	10	11
l	0	5											
	1		10										
	2		10	20									
	3			40	40								
	4			20	120	80							
	5				120	320	160						
	6				40	480	800	320					
	7					320	1600	1920	640				
	8					80	1600	4800	4480	1280			
	9						800	6400	13440	10240	2560		
	10						160	4800	22400	35840	23040	5120	
	11							1920	22400	71680	92160	51200	10240

We easily check that the graded Euler characteristic of the magnitude homology of C_5 recovers the magnitude of C_5 as follows:

$$\#C_5 = 5 - 10q + (-10 + 20)q^2 - (40 - 40)q^3 + (20 - 120 + 80)q^4 - \dots = \frac{5 - 5q}{1 + q - 2q^3}$$

(See Table 1 and Example 2.2.4). We will see below that various properties of magnitude described by Leinster, as mentioned above, are shadows of properties of magnitude homology.

Actually, Leinster first introduced the magnitude in the context of enriched categories in [2]. Generalized metric spaces are examples of enriched categories ($[0, \infty]$ -categories) and the magnitude is defined for them if they are finite. Finite graphs are generalized finite metric spaces, with distance between vertices measured as the length of a shortest path.

This thesis is laid out as follows. In section 2, we define the magnitude of a graph, expressing it as both a rational function and a formal power series over \mathbb{Z} , the most basic properties and examples of magnitude, including a simple formula for the magnitude of any graph whose automorphism group acts transitively on vertices, proving that magnitude has some basic cardinality-like properties, viewing G as a power series over \mathbb{Z} , and the inclusion-exclusion formula above. In section 3, we define the magnitude homology of graphs, showing that its graded Euler characteristic recovers the magnitude, and it satisfies categorified versions of the cardinality-like properties of magnitude, including a Kunneth theorem for

cartesian products and a Mayer-Vietoris theorem for unions. In section 4, we introduce the definition of the magnitude of enriched categories and discuss how the magnitude of graphs is introduced from that of enriched categories.

We denote \approx as isomorphisms of graphs and groups.

2 The Magnitude of Graphs

This section introduces the magnitude and the magnitude homology of a graph G , along with fundamental examples and properties. Throughout this thesis, a *graph* means a finite undirected graph with no loops or multiple edges. The set of vertices of a graph G is denoted by $V(G)$, and the set of edges of G is denoted by $E(G)$. For vertices $x, y \in V(G)$, the *distance* $d_G(x, y)$ is defined as the length of a shortest path between them, where the length of a path is the number of edges it contains. If x and y lie in different connected components of G , we set $d_G(x, y) = \infty$. Now, we say that two vertex x, y in G lie in the same connected component if there exists a path between them.

2.1 The Definition of the Magnitude of Graphs

We begin by defining the magnitude of a graph. The magnitude is defined to take values in the field of rational functions over \mathbb{Q} . It can also be interpreted as taking values in the ring of formal power series over \mathbb{Z} , a property that will be discussed in a later lemma. Let $\mathbb{Q}(q)$ denote the field of rational functions in a variable q over \mathbb{Q} . We also write $\mathbb{Z}[q]$ and $\mathbb{Z}[[q]]$ for the polynomial ring and the ring of formal power series in q over \mathbb{Z} , respectively.

Definition 2.1.1. Let G be a graph. We define the *G-matrix* $Z_G = Z_G(q)$ over $\mathbb{Z}[q]$ whose rows and columns are indexed by the vertices of G , and whose (x, y) -entry is given by

$$Z_G(q)(x, y) = q^{d(x, y)} \quad \text{for } x, y \in V(G),$$

where by convention $q^\infty = 0$.

G -matrix is the square symmetric matrix.

Proposition 2.1.2. *A G-matrix is invertible.*

Proof. By definition, the determinant of Z_G has constant term 1, which implies that $\det Z_G \neq 0$. \square

Definition 2.1.3. The *magnitude* of a graph G is defined to be the rational function given by

$$\#G(q) = \sum_{x,y \in V(G)} (Z_G(q))^{-1}(x,y).$$

Remark 2.1.4.

$$\#G(q) = \text{sum}(Z_G(q)^{-1}) = \frac{\text{sum}(\text{adj}(Z_G(q)))}{\det(Z_G(q))},$$

where adj is the adjugate matrix and sum is the sum of all entries of a matrix.

Proposition 2.1.5. $\#G(q)$ takes values in $\mathbb{Z}[[q]]$.

Proof. Let $\det Z_G(q) = 1 - qf(q)$ for some $f(q) \in \mathbb{Z}[q]$ by Proposition 2.1.2. Then we have

$$\#G(q) = \frac{\text{sum}(\text{adj}(Z_G))}{\det(Z_G)} = \text{sum}(\text{adj}(Z_G)) \sum_{n=0}^{\infty} q^n f(q)^n.$$

Note that $qf(q)$ has no constant term and then $\sum_{n=0}^{\infty} q^n f(q)^n$ takes values in $\mathbb{Z}[[q]]$. \square

Example 2.1.6. Let $G = K_3$ (complete graph with three vertices).

Figure 2: Complete graph of three vertices

Then, we can calculate the magnitude of K_3 as follows:

$$Z_{K_3}(q) = \begin{pmatrix} 1 & q & q \\ q & 1 & q \\ q & q & 1 \end{pmatrix}, \quad Z_{K_3}(q)^{-1} = \frac{1}{1 - 3q^2 + 2q^3} \begin{pmatrix} 1 - q^2 & -q + q^2 & -q + q^2 \\ -q + q^2 & 1 - q^2 & -q + q^2 \\ -q + q^2 & -q + q^2 & 1 - q^2 \end{pmatrix},$$

$$\#K_3(q) = \frac{3}{1+2q}.$$

Definition 2.1.7. Let G be a graph and $x \in V(G)$. The *weight* of x in G is defined

$$w_G(x)(q) = \sum_{y \in V(G)} (Z_G(q))^{-1}(x, y)$$

The function $w_G : V(G) \rightarrow \mathbb{Q}(q)$ is called the *weighting* on G .

The magnitude can be expressed using the weighting as follows:

$$\#G(q) = \sum_{x \in V(G)} w_G(x)$$

Lemma 2.1.8. For any graph G , the weighting w_G satisfies

$$\sum_{y \in V(G)} q^{d(x,y)} w_G(y) = 1 \quad \text{for } x \in V(G).$$

Proof. For any vertex $x \in V(G)$, we have

$$\begin{aligned} \sum_{y \in V(G)} q^{d(x,y)} w_G(y) &= \sum_{y, z \in V(G)} q^{d(x,y)} Z_G^{-1}(y, z) \\ &= \sum_{y, z \in V(G)} Z_G(x, y) Z_G^{-1}(y, z) \\ &= \sum_{z \in V(G)} \sum_{y \in V(G)} Z_G(x, y) Z_G^{-1}(y, z) \\ &= \sum_{z \in V(G)} (Z_G Z_G^{-1})(x, z) \\ &= \sum_{z \in V(G)} I(x, z) \\ &= 1. \end{aligned}$$

□

This equation is called the *weighting equation*.

Lemma 2.1.9. Let G be a graph and let $\tilde{w}_G : V(G) \rightarrow \mathbb{Q}$ be a function satisfying a weighting equation. Then, $\tilde{w}_G = w_G$. Now, w_G is the weighting on G .

Proof. Let $\mathbf{b} = (1, 1, \dots, 1)^T$ where the length of \mathbf{b} is $|V(G)|$ and $\mathbf{w}_G = (w_G(x))_{x \in V(G)}^T$. If \tilde{w}_G satisfies the weighting equation, then we have

$$Z_G \tilde{\mathbf{w}}_G = \mathbf{b}.$$

Since Z_G is invertible by Proposition 2.1.2, we have $\tilde{w}_G = w_G$. \square

This lemma shows that the weighting on a graph is unique and we use this frequently to compute the magnitude of graphs.

2.2 Basic Properties and Examples

This subsection presents fundamental properties and examples of magnitude. We focus on vertex-transitive graphs, disjoint unions, and Cartesian products. We also discuss the properties of magnitude within $\mathbb{Z}[[q]]$.

Definition 2.2.1. Let $G = (V(G), E(G))$, $H = (V(H), E(H))$ be graphs. A *graph homomorphism* from G to H is a map $f : V(G) \rightarrow V(H)$ such that if $\{x, y\} \in E(G)$ then $\{f(x), f(y)\} \in E(H)$ or $f(x) = f(y)$.

We can define a *graph automorphism* using the definition above. We denote the group of all graph automorphisms of a graph G by $\text{Aut}(G)$. $\text{Aut}(G)$ includes id_G and for $g, h \in \text{Aut}(G)$ and $x \in V(G)$, $g(h(x)) = (gh)(x)$, which means $\text{Aut}(G)$ acts on $V(G)$.

Definition 2.2.2. A graph G is *vertex-transitive* if $\text{Aut}(G)$ acts transitively on $V(G)$. It says that for any vertices x and y of G , there exists an automorphism $g : G \rightarrow G$ such that $y = g(x)$.

Lemma 2.2.3. *Let G be a vertex-transitive graph. Then,*

$$\#G(q) = \frac{|V(G)|}{\sum_{y \in V(G)} q^{d(x,y)}}$$

for any vertex $x \in V(G)$.

Proof. Let $S(x) = \sum_{y \in V(G)} q^{d(x,y)}$ for a vertex $x \in V(G)$. We show that $S(x)$ does not depend on the choice of x . Take any vertices $a, b \in V(G)$.

Since G is vertex-transitive, there exists $g \in \text{Aut}(G)$ such that $b = g(a)$. Then,

$$\begin{aligned}
S(b) &= \sum_{y \in V(G)} q^{d(b,y)} \\
&= \sum_{y \in V(G)} q^{d(g(a),y)} \\
&= \sum_{y \in V(G)} q^{d(g(a),g(y))} \quad (\text{since } g \text{ is bijective}) \\
&= \sum_{y \in V(G)} q^{d(a,y)} \quad (\text{since } g \text{ is an isomorphism}) \\
&= S(a).
\end{aligned}$$

Thus, $S(x)$ does not depend on the choice of x , denoting it by S . Now, we define a function $\tilde{w}_G : V(G) \rightarrow \mathbb{Q}(q)$ by $\tilde{w}_G(x) = \frac{1}{S}$ for any vertex $x \in V(G)$. Then \tilde{w}_G satisfies the weighting equation and by Lemma 2.1.9, we have $\#G = \frac{|V(G)|}{S}$. □

Example 2.2.4. (i) $G = V_n$ (edgeless graph with n vertices).

⊠ 3: The graph with no edges

Then, $\text{Aut}(G) \approx \mathfrak{S}_n$ and G is vertex-transitive. $S = 1$ and we have $\#V_n = n$. Now, the empty graph can be denoted by V_0 .

(ii) $G = K_n$ (complete graph with n vertices).

Then, $\text{Aut}(G) \approx \mathfrak{S}_n$ and G is vertex-transitive. $S = 1 + (n-1)q$ and we have $\#K_n = \frac{n}{1+(n-1)q}$.

(iii) $G = C_n$ (cycle graph with n vertices).

Then, $\text{Aut}(G) \approx D_{2n}$ and G is vertex-transitive. If $n = 2m$, then $S = 1 + 2(q + q^2 + \cdots + q^{m-1}) + q^m = \frac{1+q-q^m-q^{m+1}}{1-q}$. Thus, we have

图 4: Complete graph

图 5: Cycle graph

$$\#C_{2m} = \frac{2m(1-q)}{(1+q)(1-q^m)} = \frac{n(1-q)}{(1+q)(1-q^m)}. \text{ If } n = 2m - 1, \text{ then similarly}$$

$$\#C_{2m-1} = \frac{n(1-q)}{1+q-2q^m}.$$

(iv) G is the Petersen graph.

图 6: Petersen graph

Then, $\text{Aut}(G)$ contains D_{10} as its subgroup and G is vertex-transitive.
 $S = 1 + 3q + 6q^2$ and we have $\#G = \frac{10}{1+3q+6q^2}$.

(v) $G = K_{m,n}$ (complete bipartite graph).

图 7: complete bipartite graph

Then, $\text{Aut}(G) \approx \mathfrak{S}_m \times \mathfrak{S}_n$ if $m \neq n$ and G is not vertex-transitive. We can calculate the magnitude with other methods. Let a, b be the weight of vertices on each part of $K_{m,n}$. Then, the weighting equation is written by two equations as follows:

$$\begin{cases} \{q^0 + (m-1)q^2\}a + nqb = 1, \\ \{q^0 + (n-1)q^2\}b + mqa = 1. \end{cases}$$

We can solve this and we have

$$\#K_{m,n} = ma + nb = \frac{(m+n) - (2mn - m - n)q}{(1+q)(1 - (m-1)(n-1)q^2)}.$$

Lemma 2.2.5. *Let G and H be graphs. Then,*

$$\#(G \sqcup H) = \#G + \#H,$$

where $G \sqcup H$ is the disjoint union of G and H .

Proof. $Z_{G \sqcup H} = \begin{pmatrix} Z_G & O \\ O & Z_H \end{pmatrix}, Z_{G \sqcup H}^{-1} = \begin{pmatrix} Z_G^{-1} & O \\ O & Z_H^{-1} \end{pmatrix}.$

Thus,

$$\#(G \sqcup H) = \text{sum}(Z_{G \sqcup H}^{-1}) = \text{sum}(Z_G^{-1}) + \text{sum}(Z_H^{-1}) = \#G + \#H.$$

□

Definition 2.2.6. Let G and H be graphs. The *cartesian product* $G \square H$ of G and H is the graph defined as follows;

- $V(G \square H) = V(G) \times V(H)$.
- $E(G \square H) = \{\{(x, y), (x', y')\} \mid x = x' \text{ and } \{y, y'\} \in E(H) \text{ or } y = y' \text{ and } \{x, x'\} \in E(G)\}$.

Lemma 2.2.7. $\#(G \square H) = \#G \cdot \#H$.

Proof. For $x, x' \in V(G)$ and $y, y' \in V(H)$,
 $d_{G \square H}((x, y), (x', y')) = d_G(x, x') + d_H(y, y')$,
 $Z_{G \square H}((x, y), (x', y')) = q^{d_{G \square H}((x, y), (x', y'))} = q^{d_G(x, x')} q^{d_H(y, y')} = Z_G(x, x') Z_H(y, y')$,
 $Z_{G \square H} = Z_G \otimes Z_H$ and then $Z_{G \square H}^{-1} = Z_G^{-1} \otimes Z_H^{-1}$.
Thus, $\#(G \square H) = \text{sum}(Z_{G \square H}^{-1}) = \text{sum}(Z_G^{-1} \otimes Z_H^{-1}) = \text{sum}(Z_G^{-1}) \cdot \text{sum}(Z_H^{-1}) = \#G \cdot \#H$.

We used the fact that $(P \otimes Q)(R \otimes S) = (PR) \otimes (QS)$ for matrices P, Q, R , and S such that the products of PR and QS are defined. \square

Example 2.2.8. $G = K_2 \square K_3$.

$$\#K_2 \square K_3 = \#K_2 \cdot \#K_3 = \frac{2}{1+q} \cdot \frac{3}{1+2q} = \frac{6}{(1+q)(1+2q)} = \#K_{3,3}.$$

Remark 2.2.9. Here we use the catesian product for graph product, but there are other graph products. However, there is a reason that we use the catesian product. This will be clear in Section 4.

Proposition 2.2.10. *Let G be a graph. Then,*

$$\begin{aligned} \#G(q) &= \sum_{k=0}^{\infty} (-1)^k \sum_{x_0 \neq x_1 \neq \dots \neq x_k} q^{d(x_0, x_1) + d(x_1, x_2) + \dots + d(x_{k-1}, x_k)} \\ &= \sum_{n=0}^{\infty} c_n q^n, \end{aligned}$$

where

$$c_n = \sum_{k=0}^n (-1)^k |\{(x_0, \dots, x_k) \mid x_0 \neq x_1 \neq \dots \neq x_k, d(x_0, x_1) + \dots + d(x_{k-1}, x_k) = n\}|.$$

Proof. Let $\tilde{w}_G : V(G) \rightarrow \mathbb{Z}[q]$ be a map defined by

$$\tilde{w}_G(x) = \sum_{k=0}^{\infty} (-1)^k \sum_{x=x_0 \neq x_1 \neq \dots \neq x_k} q^{d(x_0, x_1) + d(x_1, x_2) + \dots + d(x_{k-1}, x_k)}.$$

Then, for $x \in V(G)$,

$$\begin{aligned}
& \sum_{y \in V(G)} q^{d(x,y)} \tilde{w}_G(y) \\
&= \tilde{w}_G(x) + \sum_{y \in V(G) \setminus \{x\}} q^{d(x,y)} \sum_{k=0}^{\infty} (-1)^k \sum_{y=x_0 \neq x_1 \neq \dots \neq x_k} q^{d(x_0, x_1) + \dots + d(x_{k-1}, x_k)} \\
&= \tilde{w}_G(x) + \sum_{k=0}^{\infty} (-1)^k \sum_{x \neq y=x_0 \neq x_1 \neq \dots \neq x_k} q^{d(x,y) + d(x_0, x_1) + \dots + d(x_{k-1}, x_k)} \\
&= \tilde{w}_G(x) + \sum_{k=0}^{\infty} (-1)^k \sum_{x \neq x_0 \neq x_1 \neq \dots \neq x_k} q^{d(x, x_0) + d(x_0, x_1) + \dots + d(x_{k-1}, x_k)} \\
&= \sum_{k=0}^{\infty} (-1)^k \sum_{x=x_0 \neq \dots \neq x_k} q^{d(x_0, x_1) + \dots + d(x_{k-1}, x_k)} \\
&\quad + \sum_{k=0}^{\infty} (-1)^k \sum_{x \neq x_0 \neq \dots \neq x_k} q^{d(x, x_0) + \dots + d(x_{k-1}, x_k)} \\
&= 1.
\end{aligned}$$

The last equality holds since the first term at k is the second term at $k-1$ in the second term with opposite sign. Now, if k goes to infinity, the term disappears since $q^\infty = 0$. Thus, by Lemma 2.1.9, we have $\tilde{w}_G = w_G$ and then the first equality of proposition follows. The second equality immediately follows from the first one. \square

Corollary 2.2.11. *Let G be a graph. $|V(G)| = \#G(0)$, $|E(G)| = -\frac{1}{2} \frac{d}{dq} \#G(q) \Big|_{q=0}$. Here, the derivative is taken in $\mathbb{Z}[[q]]$.*

Proof. From the previous proposition, we have

$$\begin{aligned}
c_0 &= \sum_{k=0}^0 (-1)^k |\{(x_0, \dots, x_k) \mid x_0 \neq x_1 \neq \dots \neq x_k, d(x_0, x_1) + \dots + d(x_{k-1}, x_k) = n\}| \\
&= |\{(x_0) \mid x_0 \in V(G)\}| \\
&= |V(G)|
\end{aligned}$$

and

$$\begin{aligned}
c_1 &= |\{(x_0) \mid d(x_0, x_0) = 1\}| - |\{(x_0, x_1) \mid x_0 \neq x_1, d(x_0, x_1) = 1\}| \\
&= 0 - 2|E(G)| \\
&= -2|E(G)|.
\end{aligned}$$

This corollary immediately follows from these results. \square

Remark 2.2.12. $c_0 \geq 0, c_1 \leq 0$, and $c_2 \geq 0$ holds. The last inequality follows from

$$c_2 = |\{(x, y, z) \mid d(x, y) = d(y, z) = 1\}| - |\{(x, y) \mid d(x, y) = 2\}|$$

by Proposition 2.2.10. However, in general, the sign of c_n is not determined. For example, if G is the Petersen graph, then $\#G = \frac{10}{1+3q+6q^2} = 10 - 30q + 30q^2 + 90q^3 - 450q^4 + \dots$. By above formula of c_2 , $c_2 = 0$ if and only if G has no cycles of length 3 and 4.

Remark 2.2.13. The magnitude does not have the data of the number of connected components. For example, let W be the graph obtained by the complete graph K_6 with a triangle of edges removed. By easy calculation,

$$\#W = \frac{6}{1+4q}.$$

Since $\#K_5 = \frac{5}{1+4q}$, we have $\#5W = \frac{30}{1+4q} = \#6K_5$. Here, nG means the disjoint union of n copies of a graph G .

2.3 Main Results on the Magnitude of Graphs

This subsection states the inclusion-exclusion principle for the magnitude of graphs under specific conditions. We begin by observing that the magnitude does not generally satisfy the inclusion-exclusion principle. We then introduce sufficient conditions for the principle to hold. In this document, we mean $G \cup H$ as a graph $(V(G) \cup V(H), E(G) \cup E(H))$.

Definition 2.3.1. Let R be a ring. A function Φ is an R -valued graph invariant if

- $\Phi(G) \in R$ for any graph G .
- If $G \approx H$ as a graph, then $\Phi(G) = \Phi(H)$.

Definition 2.3.2. Let Φ be an R -valued graph invariant.

- (1) Φ is said to be *multiplicative* if

- $\Phi(V_1) = 1$.
- $\Phi(G \square H) = \Phi(G) \cdot \Phi(H)$ for any graphs G and H .

(2) Φ is said to satisfy the *inclusion-exclusion principle* if

- $\Phi(V_0) = 0$.
- $\Phi(G \cup H) = \Phi(G) + \Phi(H) - \Phi(G \cap H)$ for any graphs G and H .

Lemma 2.3.3. *Let R be a ring containing no nonzero nilpotents and let Φ be a multiplicative R -valued graph invariant satisfying the inclusion-exclusion principle. Then, $\Phi(G) = |V(G)|$ for any graph G .*

Proof. Now, $\Phi(V_0) = 0$, $\Phi(V_1) = 1$ and by inclusion-exclusion principle, we obtain $\Phi(V_n) = n$ for any $n \geq 0$ by induction.

Let G be any graph and we fix $e \in E(G)$. Let v_e, w_e be the vertices joined by e . Consider the two subgraphs $G_e = (V(G), E(G) \setminus \{e\})$ and $H_e = (\{v_e, w_e\}, \{e\})$ of G . Then, by inclusion-exclusion principle, we have

$$\begin{aligned}\Phi(G) &= \Phi(G_e) + \Phi(H_e) - \Phi(G_e \cap H_e) \\ &= \Phi(G_e) + \Phi(K_2) - \Phi(V_2) \\ &= \Phi(G_e) + \varepsilon.\end{aligned}$$

here, we denote $\varepsilon = \Phi(K_2) - \Phi(V_2)$. Repeating this process for all edges of G , we have $\Phi(G) = \Phi(V_{V(G)}) + \varepsilon \cdot |E(G)| = |V(G)| + \varepsilon \cdot |E(G)|$.

Now, we show that $\varepsilon = 0$. Consider the graph $C_4 = K_2 \square K_2$. Now, $\Phi(C_4) = 4 + \varepsilon \cdot 4$ and by multiplicativity, we have

$$\begin{aligned}\Phi(C_4) &= \Phi(K_2) \cdot \Phi(K_2) \\ &= (\Phi(V_2) + \varepsilon)(\Phi(V_2) + \varepsilon) \\ &= 4 + 4\varepsilon + \varepsilon^2.\end{aligned}$$

We obtain $\varepsilon^2 = 0$ and then $\varepsilon = 0$ since R contains no nonzero nilpotents. Thus, we have $\Phi(G) = |V(G)|$ for any graph G . \square

The magnitude of graphs is an $\mathbb{Q}[q]$ -valued graph invariant and is multiplicative and $\#V_0 = 0$. Since $\mathbb{Q}[q]$ has no nonzero nilpotents, we have the following corollary.

Corollary 2.3.4. *The magnitude does not satisfy the inclusion-exclusion principle in general.*

Definition 2.3.5. Let X be a graph and let U be a subgraph of X . U is said to be *convex* in X if for any vertices $x, y \in V(U)$, $d_U(x, y) = d_X(x, y)$.

Lemma 2.3.6. *Let X be a graph, let G, H be subgraphs of X , $g \in V(G)$, and $h \in V(H)$ such that $X = G \cup H$ and there is a path $(g = x_0 \rightarrow x_1 \rightarrow \cdots \rightarrow x_n = h)$ in X . Then, there exists a vertex $x_i \in V(G) \cap V(H)$.*

Proof. We prove by contradiction. Let i be the largest number with $x_i \in V(G)$. If $i = n$, then $x_n \in V(G) \cap V(H)$. If $i < n$, $x_{i+1} \notin V(G)$ and $\{x_i, x_{i+1}\} \notin E(G)$, then $\{x_i, x_{i+1}\} \in E(H)$ and $x_i \in V(H)$. \square

Lemma 2.3.7. *Let X be a graph and G, H subgraphs of X such that $X = G \cup H$. If $G \cap H$ is convex in X , then G and H are also convex in X .*

Proof. We prove for G . Let $g, g' \in V(G)$. If $d_G(g, g') = \infty$, $d_G(g, g') = \infty = d_X(g, g')$. Assume that $d_X(g, g') < \infty$ and let $n = d_X(g, g')$. We can choose a shortest path $(g = x_0 \rightarrow x_1 \rightarrow \cdots \rightarrow x_n = g')$ in X such that it contains the most vertices in G . Suppose there exists a vertex $x_j \notin V(G)$ in this path. By Lemma 2.3.6, there exist vertices $x_i, x_k \in V(G) \cap V(H)$ such that $0 \leq i < j < k \leq n$. Since $G \cap H$ is convex in X , there exists a shortest path $(x_i = y_0 \rightarrow y_1 \rightarrow \cdots \rightarrow y_m = x_k)$ in $G \cap H$. Now, we obtain a path $(g = x_0 \rightarrow \cdots \rightarrow x_i = y_0 \rightarrow y_1 \rightarrow \cdots \rightarrow y_m = x_k \rightarrow \cdots \rightarrow x_n = g')$ in X which contains more vertices in G than the previous path. This is a contradiction. Thus, all vertices in the chosen path are contained in $V(G)$ and then $d_G(g, g') = d_X(g, g')$. \square

Definition 2.3.8. Let X be a graph and let U be a subgraph of X such that U is convex in X . We denote $V_U(X) = \{v \in V(X) \mid d_X(v, u) < \infty \text{ for some } u \in V(U)\}$. Then, we say that X *projects to* U if for any $x \in V_U(X)$, there exists $u' \in V(U)$ such that for any $u \in V(U)$, $d_X(x, u) = d_X(x, u') + d_X(u', u)$. For each $x \in V_U(X)$, we fix one such u' and denote it by $\pi(x)$.

Lemma 2.3.9. *If X projects to U , then $\pi(x)$ is uniquely determined for any $x \in V_U(X)$.*

Proof. Let $u_1, u_2 \in V(U)$ be vertices such that for any $u \in V(U)$,

$$\begin{aligned} d_X(x, u) &= d_X(x, u_1) + d_X(u_1, u), \\ d_X(x, u) &= d_X(x, u_2) + d_X(u_2, u). \end{aligned}$$

Then,

$$\begin{aligned} d_X(x, u_1) &= d_X(x, u_2) + d_X(u_1, u_2), \\ d_X(x, u_2) &= d_X(x, u_1) + d_X(u_2, u_1), \end{aligned}$$

and we obtain $d_X(u_1, u_2) = 0$. Thus, $u_1 = u_2$. \square

Example 2.3.10. aaa

Lemma 2.3.11. *Let X be a graph and let U be a convex subgraph of X such that X projects to U . Then, for any $u \in V(U)$,*

$$w_U(u) = \sum_{x \in \pi^{-1}(u)} q^{d_X(u, x)} w_X(x).$$

Proof. Let $\tilde{w}_U(u) = \sum_{x \in \pi^{-1}(u)} q^{d_X(u, x)} w_X(x)$ for $u \in V(U)$. Then,

$$\begin{aligned} & \sum_{v \in V(U)} q^{d_U(u, v)} \tilde{w}_U(v) \\ &= \sum_{v \in V(U)} q^{d_X(u, v)} \sum_{x \in \pi^{-1}(v)} q^{d_X(v, x)} w_X(x) \quad (\text{since } U \text{ is convex in } X.) \\ &= \sum_{v \in V(U)} \sum_{x \in \pi^{-1}(v)} q^{d_X(u, x)} w_X(x) \quad (\text{since } X \text{ projects to } U.) \\ &= \sum_{x \in V(X)} q^{d_X(u, x)} w_X(x) \\ &= 1. \end{aligned}$$

\square

The next theorem is one of the main theorems of this thesis.

Theorem 2.3.12 (Leinster [1], Theorem 4.8). *Let X be a graph and let G, H be subgraphs of X such that $X = G \cup H$. If $G \cap H$ is convex in X and H projects to $G \cap H$, then*

$$\#X = \#G + \#H - \#(G \cap H).$$

Before proving this theorem, we give the example of graphs for which we can apply this theorem.

Example 2.3.13. Let G be a graph and consider the graph H formed by identifying one of the edges of a cycle graph C_n with an edge of G . Now, let $n \geq 4$.

图 8: Cycle graph of four vertices

Then, we can apply Theorem 2.3.12 to $X = G \cup H$ as follows:

$$\#X = \#G + \#C_n - \#K_2.$$

Similarly, if G and H are graphs and $G \vee H$ is the graph formed by identifying one vertex of G with one vertex of H , then we have

$$\#(G \vee H) = \#G + \#H - 1.$$

Proof of Theorem 2.3.12. We show that

$$w_X = w_G + w_H - w_{G \cap H}, \tag{1}$$

where w_G, w_H , and $w_{G \cap H}$ are defined on $V(X)$ by extending them by zero

to the outside of each graph. If this equation holds, then

$$\begin{aligned}
\#X &= \sum_{x \in V(X)} w_X(x) \\
&= \sum_{x \in V(X)} w_G(x) + \sum_{x \in V(X)} w_H(x) - \sum_{x \in V(X)} w_{G \cap H}(x) \\
&= \#G + \#H - \#(G \cap H).
\end{aligned}$$

We now proceed to prove (1). By Lemma 2.3.7, G , H , and $G \cap H$ are convex in X . This implies that the induced metrics on these subgraphs coincide with the metric on X ; we denote this common metric by d . Let $\pi : V_{G \cap H}(H) \rightarrow V(G \cap H)$ be the projection map. We claim that

$$d(g, h) = d(g, \pi(h)) + d(\pi(h), h) \quad (2)$$

holds for any $g \in V(G)$ and $h \in V_{G \cap H}(H)$.

First, if $d(g, h) = \infty$, then (2) holds trivially by the triangle inequality. Assume that $d(g, h) < \infty$. Analogously to the proof of Lemma 2.3.7, invoking Lemma 2.3.6 guarantees the existence of a vertex $u \in V(G \cap H)$ such that $d(g, h) = d(g, u) + d(u, h)$. Then,

$$\begin{aligned}
d(g, u) + d(u, h) &= d(g, u) + d(u, \pi(h)) + d(\pi(h), h) \\
&\geq d(g, \pi(h)) + d(\pi(h), h) \\
&\geq d(g, h) \\
&= d(g, u) + d(u, h).
\end{aligned}$$

This establishes (2).

It remains to show that $w_G + w_H - w_{G \cap H}$ satisfies the weighting equation for X . That is, we show:

$$\sum_{g \in V(G)} q^{d(g, x)} w_G(g) + \sum_{h \in V(H)} q^{d(h, x)} w_H(h) - \sum_{u \in V(G \cap H)} q^{d(u, x)} w_{G \cap H}(u) = 1 \quad (3)$$

for any $x \in V(X)$. If (3) holds, then (1) follows by Lemma 2.1.8, completing the proof. Let $x \in V(X)$.

If $x \in V(G)$,

$$\begin{aligned}
& \sum_{g \in V(G)} q^{d(g,x)} w_G(g) + \sum_{h \in V(H)} q^{d(h,x)} w_H(h) - \sum_{u \in V(G \cap H)} q^{d(u,x)} w_{G \cap H}(u) \\
&= 1 + \sum_{h \in V(H)} q^{d(h,x)} w_H(h) - \sum_{u \in V(G \cap H)} q^{d(u,x)} \sum_{h \in \pi^{-1}(u)} q^{d(h,u)} w_H(h) \\
&= 1 + \sum_{h \in V_{G \cap H}(H)} q^{d(h,x)} w_H(h) - \sum_{h \in V_{G \cap H}(H)} q^{d(x, \pi(h)) + d(\pi(h), h)} w_H(h) \\
&= 1 + \sum_{h \in V_{G \cap H}(H)} q^{d(h,x)} w_H(h) - \sum_{h \in V_{G \cap H}(H)} q^{d(h,x)} w_H(h) \\
&= 1.
\end{aligned}$$

The first equality holds by $x \in V(G)$ and Lemma 2.3.11. The second equality holds by $x \in V(G)$, $q^\infty = 0$, and $h \in \pi^{-1}(u)$ means $u = \pi(h)$. The third equality holds by (2).

If $x \in V_{G \cap H}(H)$,

$$\begin{aligned}
& \sum_{g \in V(G)} q^{d(g,x)} w_G(g) + \sum_{h \in V(H)} q^{d(h,x)} w_H(h) - \sum_{u \in V(G \cap H)} q^{d(u,x)} w_{G \cap H}(u) \\
&= \sum_{g \in V(G)} q^{d(g, \pi(x)) + d(\pi(x), x)} w_G(g) + 1 - \sum_{u \in V(G \cap H)} q^{d(u, \pi(x)) + d(\pi(x), x)} w_{G \cap H}(u) \\
&= q^{d(x, \pi(x))} + 1 - q^{d(x, \pi(x))} \\
&= 1.
\end{aligned}$$

The first equality holds by $x \in V(H)$ and (2). The second equality holds by weighting equality for G and $G \cap H$.

If $x \in V(H) \setminus V_{G \cap H}(H)$,

$$\begin{aligned}
& \sum_{g \in V(G)} q^{d(g,x)} w_G(g) + \sum_{h \in V(H)} q^{d(h,x)} w_H(h) - \sum_{u \in V(G \cap H)} q^{d(u,x)} w_{G \cap H}(u) \\
&= 0 + 1 - 0 \\
&= 1.
\end{aligned}$$

This completes the proof. \square

Example 2.3.14. The three graphs below are divided into a graph C_3 , and two graphs C_2 , so they all have the same magnitude and can be calculated as follows:

$$\#G = \#C_3 + 2 \cdot \#C_2 - 2.$$

Example 2.3.15. If G is a forest, then we can calculate the magnitude of G as follows:

$$\#G = |V(G)| - 2|E(G)| \frac{q}{1+q}.$$

If G is a tree, then

$$\#G = |V(G)| - 2(|V(G)| - 1) \frac{q}{1+q}.$$

Furthermore examples.

Remark 2.3.16. Even though two graphs both have one component and the same magnitude, they may not be isomorphic. We can easily generate such examples using wedge sums of graphs as follows.

続きを書く

3 The Magnitude Homology of Graphs

In this section, we define the magnitude homology of a graph G . We provide fundamental examples and properties, and state the Mayer-Vietoris sequence for magnitude homology.

3.1 The Definition of The Magnitude Homology of Graphs

Definition 3.1.1. Let G be a graph. For a positive integer k , the *length* of a tuple (x_0, \dots, x_k) of $V(G)$ is defined to be

$$\begin{aligned} l(x_0, \dots, x_k) &= d(x_0, x_1) + d(x_1, x_2) + \dots + d(x_{k-1}, x_k) \\ &= \sum_{i=1}^k d(x_{i-1}, x_i). \end{aligned}$$

Now, let $l(x_0) = 0$. We say a tuple (x_0, \dots, x_k) is *good* if $x_0 \neq x_1 \neq \dots \neq x_k$.

Lemma 3.1.2 (Triangle inequality). *If (x_0, \dots, x_k) is a good tuple of $V(G)$, then for any $1 \leq i \leq k-1$,*

$$l(x_0, \dots, x_k) \geq l(x_0, \dots, \hat{x}_i, \dots, x_k).$$

Proof. We obviously have the statement by the triangle inequality of the distance function d . \square

Definition 3.1.3 (*Magnitude chain complex*). Let G be a graph. $MC_{*,*}(G)$ is the *magnitude complex* defined as follows:

$$MC_{*,*}(G) = \bigoplus_{l=0}^{\infty} MC_{*,l}(G).$$

For non-negative integers k and l , $MC_{k,l}(G)$ is freely generated by good tuples (x_0, \dots, x_k) of $V(G)$ of length l with the ring \mathbb{Z} . The differential $\partial : MC_{k,l}(G) \rightarrow MC_{k-1,l}(G)$ is defined by

$$\partial = \sum_{i=1}^{k-1} (-1)^{i-1} \partial_i,$$

where

$$\partial_i(x_0, \dots, x_k) = \begin{cases} (x_0, \dots, \hat{x}_i, \dots, x_k) & \text{if } l(x_0, \dots, \hat{x}_i, \dots, x_k) = l(x_0, \dots, x_k), \\ 0 & \text{otherwise.} \end{cases}$$

Remark 3.1.4. For a good tuple (x_0, \dots, x_k) and $1 \leq i \leq k-1$,

$$\partial_i(x_0, \dots, x_k) \neq 0 \iff d(x_{i-1}, x_i) + d(x_i, x_{i+1}) = d(x_{i-1}, x_{i+1}).$$

Lemma 3.1.5. $\partial \circ \partial = 0$.

Proof. Let G be a graph, let $k \geq 2, l \geq 0$, and let $(x_0, \dots, x_k) \in MC_{k,l}(G)$ be a generator. Now, we have

$$\partial_i \circ \partial_j = \partial_{j-1} \circ \partial_i \tag{4}$$

for $0 \leq i < j \leq k$. Indeed,

$$(\partial_i \circ \partial_j)(x_0, \dots, x_k) = (x_0, \dots, \hat{x}_i, \dots, \hat{x}_j, \dots, x_k) \text{ or } 0.$$

holds and

$$(\partial_{j-1} \circ \partial_i)(x_0, \dots, x_k) = (x_0, \dots, \hat{x}_i, \dots, \hat{x}_j, \dots, x_k) \text{ or } 0.$$

also holds. Furthermore,

$$\begin{aligned} & (\partial_i \circ \partial_j)(x_0, \dots, x_k) \neq 0 \\ \iff & l(x_0, \dots, \hat{x}_j, \dots, x_k) = l(x_0, \dots, \hat{x}_i, \dots, \hat{x}_j, \dots, x_k) = l \\ \iff & l(x_0, \dots, \hat{x}_i, \dots, \hat{x}_j, \dots, x_k) = l \quad (\text{using the triangle inequality.}) \\ \iff & l(x_0, \dots, \hat{x}_i, \dots, x_k) = l(x_0, \dots, \hat{x}_i, \dots, \hat{x}_j, \dots, x_k) = l \\ \iff & (\partial_{j-1} \circ \partial_i)(x_0, \dots, x_k) \neq 0, \end{aligned}$$

which induces the equation (4). Thus, we have

$$\begin{aligned} (\partial \circ \partial)(x_0, \dots, x_k) &= \sum_{i=1}^{k-2} \sum_{j=1}^{k-1} (-1)^{(i-1)+(j-1)} (\partial_i \circ \partial_j)(x_0, \dots, x_k) \\ &= \sum_{1 \leq i < j \leq k-1} (-1)^{i+j} (\partial_i \circ \partial_j)(x_0, \dots, x_k) \\ &+ \sum_{1 \leq j \leq i \leq k-2} (-1)^{i+j} (\partial_i \circ \partial_j)(x_0, \dots, x_k) \end{aligned}$$

and

$$\begin{aligned}
& \sum_{1 \leq j \leq i \leq k-2} (-1)^{i+j} (\partial_i \circ \partial_j)(x_0, \dots, x_k) \\
&= \sum_{1 \leq i \leq j \leq k-2} (-1)^{j+i} (\partial_j \circ \partial_i)(x_0, \dots, x_k) \quad (\text{switch } i \text{ and } j) \\
&= \sum_{1 \leq i \leq j'-1 \leq k-2} (-1)^{(j'-1)+i} (\partial_{j'-1} \circ \partial_i)(x_0, \dots, x_k) \quad (j' = j+1) \\
&= - \sum_{1 \leq i < j' \leq k-1} (-1)^{i+j'} (\partial_i \circ \partial_{j'})(x_0, \dots, x_k). \quad (\text{using (4)})
\end{aligned}$$

Therefore, we have $(\partial \circ \partial)(x_0, \dots, x_k) = 0$. \square

Definition 3.1.6 (*magnitude homology*). Let G be a graph. The *magnitude homology* $MH_{*,*}(G)$ of G is the homology of the magnitude chain complex $MC_{*,*}(G)$, that is,

$$MH_{k,l}(G) = \text{Ker } \partial \cap (MC_{k,l}(G)) / \text{Im } \partial \cap (MC_{k,l}(G)).$$

Example 3.1.7. (i) $G = V_n$. Then,

$$MC_{k,l}(V_n) = \begin{cases} \mathbb{Z}\{(x) \mid x \in V(V_n)\} & \text{if } k = l = 0, \\ 0 & \text{otherwise,} \end{cases}$$

and $\partial = 0$ implies that

$$MH_{k,l}(V_n) \approx \begin{cases} \mathbb{Z}^n & \text{if } k = l = 0, \\ 0 & \text{otherwise.} \end{cases}$$

(ii) $G = K_n (n \geq 2)$. Then, $l(x_0, \dots, x_k) = k$ for any good tuple (x_0, \dots, x_k) of $V(K_n)$. Thus,

$$MC_{k,l}(K_n) = \begin{cases} \mathbb{Z}\{(x_0, \dots, x_k) \mid x_0 \neq x_1 \neq \dots \neq x_k\} & \text{if } l = k, \\ 0 & \text{otherwise,} \end{cases}$$

and $\partial = 0$ implies that

$$MH_{k,l}(K_n) \approx \begin{cases} \mathbb{Z}^{n(n-1)^l} & \text{if } l = k, \\ 0 & \text{otherwise.} \end{cases}$$

(iii) $G = C_5$. Number the vertices of C_5 as shown in the following figure.

ここにナンバリングした C_5 の図を挿入

Let us consider $MH_{2,3}(C_5)$. 続く

Definition 3.1.8. Let X be a finitely generated abelian group. Then, the *rank* of X is defined by

$$\text{rank}(X) = \dim_{\mathbb{Q}}(X \otimes_{\mathbb{Z}} \mathbb{Q}).$$

In the definition above, $\text{rank}(X)$ is the number of copies of \mathbb{Z} in the decomposition of X into a direct sum of cyclic groups (using structure theorem for finitely generated abelian groups).

Theorem 3.1.9. Let G be a graph. Then,

$$\sum_{k,l \geq 0} (-1)^k \text{rank}(MH_{k,l}(G)) q^l = \#G \text{ in } \mathbb{Z}[[q]].$$

Proof.

$$\begin{aligned} \sum_{k,l \geq 0} (-1)^k \text{rank}(MH_{k,l}(G)) q^l &= \sum_{l \geq 0} \chi(MH_{*,l}(G)) q^l \\ &= \sum_{l \geq 0} \chi(MC_{*,l}(G)) q^l \\ &= \sum_{k,l \geq 0} (-1)^k \text{rank}(MC_{k,l}(G)) q^l \\ &= \sum_{k \geq 0} (-1)^k \sum_{x_0 \neq \dots \neq x_k} q^{d(x_0, x_1) + \dots + d(x_{k-1}, x_k)} \\ &= \#G. \end{aligned}$$

The last equality is obtained by Proposition 2.2.10. □

Proposition 3.1.10. Let G be a graph. Then,

- $MH_{0,0}(G) \approx \mathbb{Z}^{|V(G)|}$.
- $MH_{1,1}(G) \approx \mathbb{Z}^{2|E(G)|}$.

Proof. We calculate the magnitude homology groups directly. For $l = 0$,

$$MC_{k,0}(G) = \begin{cases} \mathbb{Z}\{(x) \mid x \in V(G)\} & \text{if } k = 0, \\ 0 & \text{otherwise,} \end{cases}$$

and $\partial = 0$ induces the first equation. For $l = 1$,

$$MC_{k,1}(G) = \begin{cases} \mathbb{Z}\{(x_0, x_1) \mid x_0 \neq x_1\} & \text{if } k = 1, \\ 0 & \text{otherwise,} \end{cases}$$

and $\partial = 0$ induces the second equation. \square

Definition 3.1.11. The diameter d of a graph G is defined by

$$d = \max\{d(x, y) \mid x, y \in V(G) \text{ and } x, y \text{ lie in the same component of } G\}.$$

If $G = V_n$, then we define $d = 0$. Then, for any graph G , $0 \leq d < \infty$ holds.

Proposition 3.1.12. *Let G be a graph and let d be the diameter of G and assume that $MH_{k,l}(G) \neq 0$ for given non-negative integers k and l . Then,*

- $\frac{l}{d} \leq k \leq l$.
- If $d > 1$ and $l > 0$, then $\frac{l}{d} < k \leq l$.

Proof. Since $MH_{k,l}(G) \neq 0$, there exists a good tuple (x_0, \dots, x_k) of length l such that $\partial(x_0, \dots, x_k) = 0$. Thus, $l = l(x_0, \dots, x_k) = \sum_{i=1}^k d(x_{i-1}, x_i) \leq \sum_{i=1}^k d = kd$ and $l = \sum_{i=1}^k d(x_{i-1}, x_i) \geq k$. This implies that $\frac{l}{d} \leq k \leq l$.

Now, assume that $d > 1$ and $l > 0$ and suppose that $k = \frac{l}{d}$. From the above discussion, we have $d(x_i, x_{i+1}) = d$ for all i . $\partial(x_0, \dots, x_k) = 0$. For the $(k+1)$ -tuple $\partial(x_0, \dots, x_k)$ is a linear combination of at most $k-1$ distinct terms of k -tuples, so $\partial(x_0, \dots, x_k) = 0$ implies $d(x_{i-1}, x_i) + d(x_i, x_{i+1}) \neq d(x_{i-1}, x_{i+1})$ for all $1 \leq i \leq k-1$. Since $d(x_0, x_1) = d \geq 2$, there exists a vertex y such that $d(x_0, y) + d(y, x_1) = d(x_0, x_1)$ and $y \neq x_0, x_1$. Then, $(x_0, y, x_1, \dots, x_k)$ is a good tuple in $MC_{k+1,l}(G)$ and

$$\partial_i(x_0, y, x_1, \dots, x_k) = \begin{cases} (x_0, x_1, \dots, x_k) & \text{for } i = 1, \\ 0 & \text{for } 2 \leq i \leq k. \end{cases}$$

It is obvious for $3 \leq i$ by $d(x_{i-1}, x_i) + d(x_i, x_{i+1}) \neq d(x_{i-1}, x_{i+1})$ and is also true for $i = 2$ since $d(y, x_1) + d(x_1, x_2) = d(y, x_1) + d > d \geq d(y, x_2)$. This implies $MH_{k,l}(G) = 0$ and contradicts the assumption. \square

3.2 Induced Maps on Magnitude Homology

Definition 3.2.1. Let G and H be graphs. A map $f : V(G) \rightarrow V(H)$ is said to be a *graph map* if for any $\{x, y\} \in E(G)$, either $f(x) = f(y)$ or $\{f(x), f(y)\} \in E(H)$.

We note that a graph map is distinguished from a graph homomorphism, which requires that $\{f(x), f(y)\} \in E(H)$ for any $\{x, y\} \in E(G)$.

Proposition 3.2.2. $l(f(x_0), \dots, f(x_k)) \leq l(x_0, \dots, x_k)$ for any good tuple (x_0, \dots, x_k) of $V(G)$.

Proof. For any vertices $x, y \in V(G)$, $d_H(f(x), f(y)) \leq d_G(x, y)$ holds. Indeed, if x, y lie in the same component of G , then there exists a path $(x = x_0 \rightarrow x_1 \rightarrow \dots \rightarrow x_n = y)$ in G such that $n = d_G(x, y)$. Since f is a graph map, either $f(x_{i-1}) = f(x_i)$ or $\{f(x_{i-1}), f(x_i)\} \in E(H)$ for any $1 \leq i \leq n$. Thus, $(f(x) = f(x_0) \rightarrow f(x_1) \rightarrow \dots \rightarrow f(x_n) = f(y))$ is a path in H and then $d_H(f(x), f(y)) \leq n = d_G(x, y)$. If x, y do not lie in the same component, then $d_G(x, y) = d_H(f(x), f(y)) = \infty$. Then,

$$\begin{aligned} l(f(x_0), \dots, f(x_k)) &= \sum_{i=1}^k d_H(f(x_{i-1}), f(x_i)) \\ &\leq \sum_{i=1}^k d_G(x_{i-1}, x_i) \\ &= l(x_0, \dots, x_k). \end{aligned}$$

□

Definition 3.2.3. Let G and H be graphs and let $f : V(G) \rightarrow V(H)$ be a graph map. Then, the *induced map* $f_{\#} : MC_{*,*}(G) \rightarrow MC_{*,*}(H)$ is defined by

$$f_{\#}(x_0, \dots, x_k) = \begin{cases} (f(x_0), \dots, f(x_k)) & \text{if } l(f(x_0), \dots, f(x_k)) = l(x_0, \dots, x_k), \\ 0 & \text{otherwise.} \end{cases}$$

for any good tuple (x_0, \dots, x_k) of $V(G)$.

Lemma 3.2.4. Let G and H be graphs and let $f : V(G) \rightarrow V(H)$ be a map. Then, f is a graph map if and only if $d_H(f(x), f(y)) \leq d_G(x, y)$ for any $x, y \in V(G)$.

Proof. Let $x, y \in V(G)$ such that $d_G(x, y) = n < \infty$. There exists a shortest path $(x = x_0 \rightarrow x_1 \rightarrow \cdots \rightarrow x_n = y)$. For each $i = 0, \dots, n-1$, $d_H(f(x_i), f(x_{i+1})) \leq d_G(x_i, x_{i+1}) = 1$ holds and then

$$d_H(f(x), f(y)) \leq \sum_{i=0}^{n-1} d_H(f(x_i), f(x_{i+1})) \leq \sum_{i=0}^{n-1} d_G(x_i, x_{i+1}) = d_G(x, y).$$

□

Proposition 3.2.5. *The induced map $f_{\#} : MC_{*,*}(G) \rightarrow MC_{*,*}(H)$ is a chain map.*

Proof. We need to show that the following diagram commutes for any $k, l \geq 0$.

$$\begin{array}{ccccccc} \cdots & \longrightarrow & MC_{k,l}(G) & \xrightarrow{\partial} & MC_{k-1,l}(G) & \longrightarrow & \cdots \\ & & \downarrow f_{\#}^{k,l} & \circlearrowleft & \downarrow f_{\#}^{k-1,l} & & \\ \cdots & \longrightarrow & MC_{k,l}(H) & \xrightarrow{\partial} & MC_{k-1,l}(H) & \longrightarrow & \cdots \end{array}$$

Let (x_0, \dots, x_k) be a generator of $MC_{k,l}(G)$.

If $l(x_0, \dots, x_k) = l(x_0, \dots, \hat{x}_i, \dots, x_k) = l(f(x_0), \dots, f(\hat{x}_i), \dots, f(x_k))$,

$$\begin{aligned} f_{\#} \circ \partial_i(x_0, \dots, x_k) &= f_{\#}(x_0, \dots, \hat{x}_i, \dots, x_k) \\ &= (f(x_0), \dots, f(\hat{x}_i), \dots, f(x_k)), \end{aligned}$$

and otherwise it vanishes by definition.

If $l(x_0, \dots, x_k) = l(f(x_0), \dots, f(x_k)) = l(f(x_0), \dots, f(\hat{x}_i), \dots, f(x_k))$,

$$\begin{aligned} \partial_i \circ f_{\#}(x_0, \dots, x_k) &= \partial_i(f(x_0), \dots, f(x_k)) \\ &= (f(x_0), \dots, f(\hat{x}_i), \dots, f(x_k)). \end{aligned}$$

and otherwise it vanishes.

Consequently, the two terms agree provided they are non-vanishing. Moreover, the conditions for non-vanishing are equivalent by Proposition 3.2.2.

Indeed, we have $l(f(x_0), \dots, f(x_k)) \leq l(x_0, \dots, x_k)$ and then

$$\begin{aligned}
& l(x_0, \dots, x_k) = l(x_0, \dots, \hat{x}_i, \dots, x_k) = l(f(x_0), \dots, f(\hat{x}_i), \dots, f(x_k)) \\
& \iff l(x_0, \dots, x_k) = l(x_0, \dots, \hat{x}_i, \dots, x_k) = l(f(x_0), \dots, f(\hat{x}_i), \dots, f(x_k)) \\
& \quad \leq l(f(x_0), \dots, f(x_k)) \leq l(x_0, \dots, x_k) \\
& \iff l(x_0, \dots, x_k) = l(x_0, \dots, \hat{x}_i, \dots, x_k) = l(f(x_0), \dots, f(\hat{x}_i), \dots, f(x_k)) \\
& \quad = l(f(x_0), \dots, f(x_k)) \\
& \iff l(x_0, \dots, x_k) = l(f(x_0), \dots, f(x_k)) = l(f(x_0), \dots, f(\hat{x}_i), \dots, f(x_k))
\end{aligned}$$

holds. Thus, we have the commutativity of the diagram. \square

Definition 3.2.6 (Induced maps in homology). If $f : G \rightarrow H$ is a graph map, the *induced map in homology* $f_* : MH_{*,*}(G) \rightarrow MH_{*,*}(H)$ is the map induced by the chain map $f_\# : MC_{*,*}(G) \rightarrow MC_{*,*}(H)$.

Definition 3.2.7. A is called a *bigraded abelian group* if $A = \bigoplus_{k,l \geq 0} A_{k,l}$ where each $A_{k,l}$ is an abelian group. A *bigraded homomorphism* $f : A \rightarrow B$ between bigraded abelian groups A and B is a homomorphism such that $f(A_{k,l}) \subset B_{k,l}$ for any $k, l \geq 0$.

Proposition 3.2.8. The assignment $G \mapsto MH_{*,*}(G)$ and $f \mapsto f_*$ defines a functor from the category of graphs and graph maps to the category of bigraded abelian groups and bigraded homomorphisms, denoting by $\mathbf{Graph} \rightarrow \mathbf{BAb}$.

Proposition 3.2.9. Let $f : G \rightarrow H$ be a graph map.

- $f_* : MH_{0,0}(G) \rightarrow MH_{0,0}(H)$ is given by $f_*(x) = f(x)$ for any $x \in V(G)$.
- $f_* : MH_{1,1}(G) \rightarrow MH_{1,1}(H)$ is given by

$$f_*(x_0, x_1) = \begin{cases} (f(x_0), f(x_1)) & \text{if } f(x_0) \neq f(x_1), \\ 0 & \text{otherwise.} \end{cases}$$

for any $(x_0, x_1) \in MH_{1,1}(G)$.

Proof. The first equation is obvious.

For the second equation, we obtain by definition;

$$f_*(x_0, x_1) = \begin{cases} (f(x_0), f(x_1)) & \text{if } l(f(x_0), f(x_1)) = l(x_0, x_1) = 1, \\ 0 & \text{otherwise.} \end{cases}$$

for any $(x_0, x_1) \in MH_{1,1}(G)$. Since f is a graph map, $l(f(x_0), f(x_1)) = 1$ if and only if $f(x_0) \neq f(x_1)$. \square

Corollary 3.2.10. *Let $f : G \rightarrow H$ be a graph map. f_* is an isomorphism if and only if f is a graph isomorphism.*

Proof. If f is a graph isomorphism, then the chain map $f_\#$ is obviously bijective, which implies that f_* is an isomorphism. Let f be a graph map such that f_* is an isomorphism. By Proposition 3.2.9, the isomorphism $f_* : MH_{0,0}(G) \rightarrow MH_{0,0}(H)$ means that $f : V(G) \rightarrow V(H)$ is bijective, and the isomorphism $f_* : MH_{1,1}(G) \rightarrow MH_{1,1}(H)$ means that for any $\{x, y\} \in E(G)$, $l(f(x), f(y)) = l(x, y) = 1$ and then $\{f(x), f(y)\} \in E(H)$. Similarly, for any $\{u, v\} \in E(H)$, there exists $\{x, y\} \in E(G)$ such that $f(x) = u$ and $f(y) = v$ by using f_*^{-1} . Thus, f is a graph isomorphism. \square

3.3 Magnitude Homology of Disjoint Union of Graphs

Proposition 3.3.1. *Let G and H be graphs. We define the inclusion graph maps $i : G \rightarrow G \sqcup H, j : H \rightarrow G \sqcup H$. Then,*

$$i_* \oplus j_* : MH_{*,*}(G) \oplus MH_{*,*}(H) \rightarrow MH_{*,*}(G \sqcup H)$$

is an isomorphism for each $k, l \geq 0$.

Proof. • **Surjectivity.** Let $(x_0, \dots, x_k) \in MH_{k,l}(G \sqcup H)$ be a generator. By $l(x_0, \dots, x_k) = l$, $d(x_j, x_{j+1}) \leq \infty$ for any $0 \leq j \leq k-1$. Then, $\{x_0, \dots, x_k\} \subset V(G)$ or $\{x_0, \dots, x_k\} \subset V(H)$. Assume that $\{x_0, \dots, x_k\} \subset V(G)$. Then, $(i_* \oplus j_*)((x_0, \dots, x_k), 0) = (x_0, \dots, x_k)$.

• **Injectivity.** Assume that there are generators $((x_0, \dots, x_{k_1}), (y_0, \dots, y_{k_2})) \in MH_{*,*}(G) \oplus MH_{*,*}(H)$ such that $(i_* \oplus j_*)((x_0, \dots, x_{k_1}), (y_0, \dots, y_{k_2})) =$

0.

$$\begin{aligned}
& (i_* \oplus j_*)((x_0, \dots, x_{k_1}), (y_0, \dots, y_{k_2})) = 0 \\
& \Rightarrow i_*((x_0, \dots, x_{k_1})) + j_*((y_0, \dots, y_{k_2})) = 0 \\
& \Rightarrow (x_0, \dots, x_{k_1}) + (y_0, \dots, y_{k_2}) = 0
\end{aligned}$$

in $MH_{*,*}(G \sqcup H)$. Now, since $\{x_0, \dots, x_{k_1}\} \subset V(G)$ and $\{y_0, \dots, y_{k_2}\} \subset V(H)$, there is no cancellation between the two terms. Contradiction.

□

We can give another proof of Lemma 2.2.5 by Proposition 3.3.1 and $\chi(A_* \oplus B_*) = \chi(A_*) + \chi(B_*)$.

3.4 Magnitude Homology of Cartesian Products

Definition 3.4.1. This definition is not true. Fix $l \geq 0$. The *exterior product* is the map

$$\square : MC_{*,*}(G) \otimes MC_{*,*}(H) \rightarrow MC_{*,*}(G \square H)$$

is defined as follows. Let \square be the map

$$\square : MC_{k_1, l_1}(G) \times MC_{k_2, l_2}(H) \rightarrow MC_{k, l}(G \square H) \text{ for } k_1, k_2 \geq 0, k = k_1 + k_2, l = l_1 + l_2,$$

which is defined by

$$\square((x_0, \dots, x_{k_1}), (y_0, \dots, y_{k_2})) = \sum_{\sigma} \text{sign}(\sigma)((x_{i_0}, y_{j_0}), (x_{i_1}, y_{j_1}), \dots, (x_{i_k}, y_{j_k})),$$

where the sum is over all shuffles σ of type (k_1, k_2) , that is, all sequences

$$((i_0, j_0), (i_1, j_1), \dots, (i_k, j_k))$$

such that

$$i_0 = 0, j_0 = 0, 0 \leq i_r \leq k_1, 0 \leq j_r \leq k_2 \text{ for } 0 \leq r \leq k, \text{ and}$$

$$(i_{r+1}, j_{r+1}) = \begin{cases} (i_r + 1, j_r) & \text{or} \\ (i_r, j_r + 1) & \text{for } 0 \leq r < k, \end{cases}$$

and

$$\text{sign}(\sigma) = (-1)^m,$$

where $m = \#\{(i, j) \in \{\{0, \dots, k_1\} \times \{0, \dots, k_2\}\} \mid i = i_r \Rightarrow j < j_r\}$.

Here, we extend the map \square bilinearly to the tensor product

$$MC_{k_1, l_1}(G) \otimes MC_{k_2, l_2}(H) \rightarrow MC_{k, l}(G \square H)$$

.

We denote this induced map also by \square and call it the *exterior product*.

Example 3.4.2. Let $G = C_2 \square C_2 = C_4$.

⊠ 9: Square graph

Consider the exterior product $\square((x_0, x_1) \otimes (y_0, y_1))$. We have the two shuffles of type $(1, 1)$:

$$((0, 0), (1, 0), (1, 1)), ((0, 0), (0, 1), (1, 1)).$$

Thus,

$$\square((x_0, x_1) \otimes (y_0, y_1)) = -((x_0, y_0), (x_1, y_0), (x_1, y_1)) + ((x_0, y_0), (x_0, y_1), (x_1, y_1)).$$

Remark 3.4.3. As you see in the above example, the number of shuffles is $\binom{k}{k_1}$.

Proposition 3.4.4. *The exterior product $\square : MC_{*,*}(G) \otimes MC_{*,*}(H) \rightarrow MC_{*,*}(G \square H)$ is a chain map.*

Proof. Let $\mathbf{x} = (\mathbf{x}_0, \dots, \mathbf{x}_{k_1}), \mathbf{y} = (\mathbf{y}_0, \dots, \mathbf{y}_{k_2})$. Now, we show that

$$(\partial \circ \square)(\mathbf{x} \otimes \mathbf{y}) = \square((\partial \mathbf{x}) \otimes \mathbf{y}) + (-1)^{k_1} \square(\mathbf{x} \otimes (\partial \mathbf{y})) = (\square \circ (\partial \otimes \partial))(\mathbf{x} \otimes \mathbf{y}).$$

Here, we should consider the sequence of tensor products of the magnitude chain complexes defined by

$$\begin{aligned}\partial \otimes \partial : MC_{k_1, l_1}(G) \otimes MC_{k_2, l_2}(H) &\rightarrow (MC_{k_1-1, l_1}(G) \otimes MC_{k_2, l_2}(H)) \\ &\quad \oplus (MC_{k_1, l_1}(G) \otimes MC_{k_2-1, l_2}(H)), \\ (\partial \otimes \partial)(\mathbf{x} \otimes \mathbf{y}) &= (\partial \mathbf{x}) \otimes \mathbf{y} + (-1)^{k_1} \mathbf{x} \otimes (\partial \mathbf{y}).\end{aligned}$$

Then, we should show only the first equality.

ここに可換図式を挿入. 証明も続く \square

From this proposition, we obtain the induced map in homology, also denoting \square .

Definition 3.4.5. (Tor functor) Let R be a ring and let A, B be R -modules. Then, $\text{Tor}(A, B)$ is defined by the derived functor of the tensor product.

Theorem 3.4.6 (Hepworth, Willerton [3], Theorem 5.3). *Let G and H be graphs.*

$$0 \rightarrow MH_{*,*}(G) \otimes MH_{*,*}(H) \xrightarrow{\square} MH_{*,*}(G \square H) \rightarrow \text{Tor}(MH_{*-1,*}(G), MH_{*,*}(H)) \rightarrow 0$$

is a short exact sequence and non-naturally split. In particular, if $MH_{,*}(G)$ or $MH_{*,*}(H)$ is torsion-free, then the exterior product \square is an isomorphism.*

We don't prove this theorem in this thesis.

Example 3.4.7. $G = C_4 = C_2 \square C_2$.

3.5 The Mayer-Vietoris Sequence of Magnitude Homology of Graphs

Definition 3.5.1. Let X be a graph and let G, H be subgraphs of X .

- (1) $(X; G, H)$ is said to be a *projecting decomposition* if $X = G \cup H$, $G \cap H$ is convex in X and H projects to $G \cap H$.

We write $i^G : G \rightarrow X$, $i^H : H \rightarrow X$, $j^G : G \cap H \rightarrow G$, $j^H : G \cap H \rightarrow H$ for the inclusion graph maps.

- (2) Let $(X; G, H), (X'; G', H')$ be projecting decompositions. $f : (X; G, H) \rightarrow (X'; G', H')$ is said to be a *decomposition map* if $f : X \rightarrow X'$ is a graph map such that $f(V(G)) \subset V(G')$ and $f(V(H)) \subset V(H')$.
- (3) Let $f : (X; G, H) \rightarrow (X'; G', H')$ be a decomposition map. Then, f is said to be a *projecting decomposition map* if $V_{G \cap H}(H) = f^{-1}(V_{G' \cap H'}(H'))$ and $f(\pi(h)) = \pi(f(h))$ for any $h \in V_{G \cap H}(H)$.
- (4) Let $(X; G, H)$ be a projecting decomposition. $MC_{*,*}(G, H)$ denote the subcomplex of $MC_{*,*}(X)$ spanned by good tuples (x_0, \dots, x_k) whose entries all lie in G or all lie in H .

Theorem 3.5.2. *Let $(X; G, H)$ be a projecting decomposition. Then, the inclusion map*

$$MC_{*,l}(G, H) \hookrightarrow MC_{*,l}(X)$$

is a quasi-isomorphism for any $l \geq 0$.

Theorem 3.5.3 (Hepworth, Willerton [3], Theorem 6.6). *Let $(X; G, H)$ be a projecting decomposition. Then,*

$$0 \rightarrow MH_{*,*}(G \cap H) \xrightarrow{(j_*^G, -j_*^H)} MH_{*,*}(G) \oplus MH_{*,*}(H) \xrightarrow{i_*^G \oplus i_*^H} MH_{*,*}(X) \rightarrow 0$$

is a split short exact sequence.

We don't prove these theorems in this thesis.

Corollary 3.5.4. *Let $(X; G, H)$ be a projecting decomposition. Then,*

$$\#X = \#G + \#H - \#(G \cap H)$$

in $\mathbb{Z}[[q]]$.

Proof. By Theorem 3.5.3,

$$\chi(MH_{*,l}(G \cap H)) - \chi((MH_{*,l}(G)) \oplus MH_{*,l}(H)) + \chi(MH_{*,l}(X)) = 0 \text{ holds and then}$$

$$\chi(MH_{*,l}(X)) = \chi(MH_{*,l}(G)) + \chi(MH_{*,l}(H)) - \chi(MH_{*,l}(G \cap H)).$$

For each $l \geq 0$, multiplying by q^l and summing over all $l \geq 0$, we have

$$\sum_{l \geq 0} \chi(MH_{*,l}(X))q^l = \sum_{l \geq 0} \chi(MH_{*,l}(G))q^l + \sum_{l \geq 0} \chi(MH_{*,l}(H))q^l - \sum_{l \geq 0} \chi(MH_{*,l}(G \cap H))q^l.$$

By Theorem 3.1.9, we obtain the desired equation. \square

3.6 Diagonal Graphs and its Property

Definition 3.6.1. A graph G is said to be *diagonal* if $MH_{k,l}(G) = 0$ for $k \neq l$.

Proposition 3.6.2. *Any trees are diagonal.*

Proof. aaa

□

Proposition 3.6.3. *For a diagonal graph, the magnitude completely determines the magnitude homology ranks.*

Proof. By Theorem 3.1.9, for a diagonal graph G ,

$$\begin{aligned}\#G &= \sum_{l \geq 0} \chi(MH_{*,l}(G))q^l \\ &= \sum_{l \geq 0} (-1)^l \text{rank}(MH_{l,l}(G))q^l.\end{aligned}$$

Thus, the magnitude $\#G$ determines $\text{rank}(MH_{l,l}(G))$ for each $l \geq 0$. □

4 Motivation: The Magnitude of Enriched Categories

In this section, we explain the motivation for studying the magnitude of graphs in a broader context. We employ the notion of enriched categories to define the magnitude.

4.1 The Magnitude of a Matrix

Definition 4.1.1. Let k be a set and let $+, \cdot$ be binary operations on k , and let $0_k, 1_k$ be elements of k . Then, $(k, +, \cdot, 0_k, 1_k)$ is called a *rig* if the following conditions hold:

- (1) $(k, +, 0_k)$ is a commutative monoid.
- (2) $(k, \cdot, 1_k)$ is a monoid.
- (3) multiplication distributes over addition, that is, for any $a, b, c \in k$,

$$a \cdot (b + c) = a \cdot b + a \cdot c, \quad (a + b) \cdot c = a \cdot c + b \cdot c.$$

Now, we mean a rig as a commutative rig with the operation \cdot .

Example 4.1.2. $(\mathbb{Z}_{\geq 0}, +, \cdot, 0, 1)$ is a rig.

Definition 4.1.3. Let k be a rig and let I, J be finite sets. An $I \times J$ -matrix is a function $\zeta : I \times J \rightarrow k$.

Definition 4.1.4. Let k be a rig, and let I, J , and L be finite sets.

- (1) If ζ_1 is an $I \times J$ -matrix and ζ_2 is a $J \times L$ -matrix, then the product $\zeta_1 \zeta_2$ is defined as follows:

$$(\zeta_1 \zeta_2)(i, l) = \sum_{j \in J} \zeta_1(i, j) \cdot \zeta_2(j, l) \quad (i \in I, l \in L)$$

- (2) $\delta : I \times I \rightarrow k$ is called the *identity matrix* if $\delta(i, j) = 1_k$ when $i = j$ and $\delta(i, j) = 0_k$ when $i \neq j$.

- (3) Let $\zeta : I \times J \rightarrow k$ be a matrix. We define $\zeta^* : J \times I \rightarrow k$ by $\zeta^*(j, i) = \zeta(i, j)$.
- (4) Let ζ be an $I \times I$ -matrix. If there exists an $I \times I$ -matrix ζ^{-1} such that $\zeta\zeta^{-1} = \delta$ and $\zeta^{-1}\zeta = \delta$, then ζ is said to be *invertible* and ζ^{-1} is called the *inverse* of ζ .
- (5) $w : I \rightarrow k$ is called a *vector*. If ζ is an $I \times J$ -matrix, v is a I -vector, and w is a J -vector, then the products $\zeta w : I \rightarrow k$ and $v\zeta : J \rightarrow k$ are defined by

$$(\zeta w)(i) = \sum_{j \in J} \zeta(i, j) \cdot w(j) \quad (i \in I)$$

$$(v\zeta)(j) = \sum_{i \in I} v(i) \cdot \zeta(i, j) \quad (j \in J)$$

Now, ζw is an I -vector and $v\zeta$ is a J -vector.

- (6) If w, v are I -vectors, then the *inner product* vw is defined by

$$vw = \sum_{i \in I} v(i) \cdot w(i)$$

- (7) Let u_I be the I -vector defined by $u(i) = 1_k$ for any $i \in I$.

Definition 4.1.5. Let ζ be an $I \times I$ -matrix over a rig k .

- A *weighting* on ζ is a vector $w : J \rightarrow k$ such that $\zeta w = u_I$. $w(j)$ is called the *weight* of $j \in J$.
- A *coweighting* on ζ is a vector $v : I \rightarrow k$ such that $v\zeta = u_I^*$. $v(i)$ is called the *coweight* of $i \in I$.

Example 4.1.6. Let G be a graph. Then, $Z_G(q)$ is a $V(G) \times V(G)$ -matrix over the rig $\mathbb{Q}[[q]]$ and the weighting on $Z_G(q)$ is the weighting on G defined in Section 2.1.

Lemma 4.1.7. Let ζ be an $I \times I$ -matrix over a rig k . If ζ has a weighting w and a coweighting v , then

$$\sum_{i \in I} v(i) = \sum_{j \in J} w(j)$$

Proof.

$$\begin{aligned}
\sum_{i \in I} v(i) &= vu_I \\
&= v(\zeta w) \\
&= (v\zeta)w \\
&= u_J w \\
&= \sum_{j \in J} w(j)
\end{aligned}$$

□

From this lemma, the sum of the weighting or coweighting on ζ is unique if they exist. Therefore, we can define the magnitude of ζ as follows:

Definition 4.1.8. Let ζ be an $I \times J$ -matrix over a rig k . If ζ has a weighting and a coweighting, then the *magnitude* of ζ is defined to be

$$\#\zeta = \sum_{i \in I} v(i) = \sum_{j \in J} w(j),$$

where w is the weighting on ζ and v is the coweighting on ζ .

Lemma 4.1.9. Let ζ be an $I \times I$ -matrix over a rig k .

- (1) If ζ is invertible, then ζ has the magnitude.
- (2) If k is a field and ζ has the magnitude, then ζ is invertible.

Proof. (1) If ζ is invertible, then $w = \zeta^{-1}u_I$ and $v = u_I\zeta^{-1}$ obviously satisfy the definition of weighting and coweighting respectively. Thus ζ has the magnitude by Lemma 4.1.7.

(2) If k is a field and ζ has the magnitude, then there exist a weighting w and a coweighting v on ζ . Let ζx be a zero-map for some $x : I \rightarrow k$. Then,

$$0 = v(\zeta x) = (v\zeta)x = u_I x = \sum_{i \in I} x(i)$$

ここからやり直し

□

Lemma 4.1.10. *Let ζ be an invertible $I \times I$ -matrix over a rig k . Then, ζ has the unique weighting w of ζ , given by $w(j) = \sum_{i \in I} \zeta^{-1}(j, i)$ for $j \in I$, and the unique coweighting v of ζ , given by $v(i) = \sum_{j \in I} \zeta^{-1}(j, i)$ for $i \in I$. Then,*

$$\#\zeta = \sum_{i, j \in I} \zeta^{-1}(j, i)$$

Proof. We should check the uniqueness and it holds from the invertibility of ζ . \square

4.2 The Definition of Enriched Categories

In this document, we only treat *locally small* categories. Now, a category \mathcal{C} is locally small if for any objects a, b of \mathcal{C} , the hom-set $\text{Hom}_{\mathcal{C}}(a, b)$ forms a set.

Definition 4.2.1. A category \mathcal{C} is called a *monoid* if \mathcal{C} has only one object $*$ and $V = \text{Hom}_{\mathcal{C}}(*, *)$ is a monoid with the composition of morphisms as the binary operation and the identity morphism id_* as the identity element. We denote the operation of V by \otimes .

ここに可換図式を挿入

Definition 4.2.2. A pair $(\mathcal{V}, \otimes, I, \alpha, \lambda, \rho)$ is called a *monoidal category* if it satisfies the following conditions:

- (1) \mathcal{V} is a category.
- (2) $\otimes : \mathcal{V} \times \mathcal{V} \rightarrow \mathcal{V}$ is a functor.
- (3) I is an object of \mathcal{V} .
- (4) α is the natural isomorphism $\otimes \circ (\otimes \times id_{\mathcal{V}}) \Rightarrow \otimes \circ (id_{\mathcal{V}} \times \otimes)$ given by $\alpha_{uvw} : (u \otimes v) \otimes w \xrightarrow{\sim} u \otimes (v \otimes w)$.
- (5) λ is the natural isomorphism $I \otimes - \Rightarrow id_{\mathcal{V}}$ given by $\lambda_u : I \otimes u \xrightarrow{\sim} u$.
- (6) ρ is the natural isomorphism $- \otimes I \Rightarrow id_{\mathcal{V}}$ given by $\rho_u : u \otimes I \xrightarrow{\sim} u$.
- (7) The following diagram commutes for any objects u, v, w, x of \mathcal{V} :
ここに可換図式を挿入

- (8) The following diagrams commute for any objects u, v of \mathcal{V} : ここに可換図式を挿入

We also call \mathcal{V} a monoidal category, omitting \otimes and I .

Example 4.2.3. (i) $(\mathbf{Set}, \times, \{*\})$ is a monoidal category. ここに説明を挿入

- (ii) $(\mathbf{Vect}_K, \otimes_K, K)$ is a monoidal category, where K is a field. ここに説明を挿入

- (iii) $([0, \infty], +, 0)$ is a monoidal category. ここに説明を挿入

- (iv) $(\mathbf{2}, \otimes, t)$ is a monoidal category, where $\mathbf{2}$ is the category defined by $Ob(\mathbf{2}) = \{t, f\}$ and the morphism sets are defined by

$hom_{\mathbf{2}}$	t	f
t	$\{id_t\}$	\emptyset
f	$\{*\}$	$\{id_f\}$

and the operation \otimes is defined by the following table:

\otimes	t	f
t	t	f
f	f	f

ここに説明を挿入

Then, $\mathbf{2}$ is a monoidal subcategory of $[0, \infty]$ by the embedding $t \mapsto 0, f \mapsto \infty$ and of Set by the embedding $t \mapsto \{*\}, f \mapsto \emptyset$.

Definition 4.2.4. An *enriched category* \mathcal{A} in a monoidal category $(\mathcal{V}, \otimes, I)$ is defined as follows:

- (1) For any objects a, b of \mathcal{A} , $Hom_{\mathcal{A}}(a, b)$ is an object of \mathcal{V} .
- (2) For any objects a, b, c of \mathcal{A} , there exists a morphism $m_{abc} : Hom_{\mathcal{A}}(b, c) \otimes Hom_{\mathcal{A}}(a, b) \rightarrow Hom_{\mathcal{A}}(a, c)$ in \mathcal{V} , which defines the composition of morphisms.

- (3) For any object a of \mathcal{A} , there exists a morphism $j_a : I \rightarrow \text{Hom}_{\mathcal{A}}(a, a)$ in \mathcal{V} , which defines the identity morphism of a . あと3つの可換図式を挿入

Then, \mathcal{A} is called a \mathcal{V} -category.

Definition 4.2.5. Let $\mathcal{A}, \mathcal{A}'$ be \mathcal{V} -categories. A functor $F : \mathcal{A} \rightarrow \mathcal{A}'$ is called a \mathcal{V} -functor if it satisfies the following conditions. We denote $F_{ab} : \text{Mor}_{\mathcal{A}}(a, b) \rightarrow \text{Mor}_{\mathcal{A}'}(F(a), F(b))$ as the morphism function.

- (1) The following diagram commutes for any objects a, b, c of \mathcal{A} : ここに可換図式を挿入
- (2) The following diagram commutes for any object a of \mathcal{A} : ここに可換図式を挿入

Remark 4.2.6. The family of all \mathcal{V} -categories and \mathcal{V} -functors form a category, which is denoted by $\mathcal{V}\text{-Cat}$.

Example 4.2.7. aaa

4.3 The Magnitude of Enriched Categories

Definition 4.3.1. Let \mathcal{C} be a category. The *isomorphism classes* of objects of \mathcal{C} is defined by the quotient classes $\text{Ob}(\mathcal{C})/\approx$, where $a \approx b$ if and only if there exists an isomorphism $f : a \rightarrow b$ in \mathcal{C} .

In this section, we consider only monoidal categories $(\mathcal{V}, \otimes, I)$ satisfying that \mathcal{V}/\approx forms a set.

Lemma 4.3.2. Let $(\mathcal{V}, \otimes, I)$ be a monoidal category. Then, the binary operation \otimes on \mathcal{V} induces a monoid structure on $\text{Ob}(\mathcal{V})/\approx$, that is, $(\text{Ob}(\mathcal{V})/\approx, \otimes, I)$ is a monoid.

Proof. aaa. □

Definition 4.3.3. Let $(\mathcal{V}, \otimes, I)$ be a monoidal category and let k be a rig. We define a monoid homomorphism

$$|\cdot| : (\text{Ob}(\mathcal{V})/\approx, \otimes, I) \rightarrow (k, \cdot, 1_k)$$

such that $|I| = 1_k$ and $|u \otimes v| = |u| \cdot |v|$ for any objects u, v of \mathcal{V} .

Example 4.3.4. aaa.

Definition 4.3.5. Let \mathcal{V} be a monoidal category and let \mathcal{A} be a \mathcal{V} -category which has finitely many objects.

- (1) An $\mathcal{O}b(\mathcal{A}) \times \mathcal{O}b(\mathcal{A})$ -matrix $\zeta_{\mathcal{A}}$ is defined by

$$\zeta_{\mathcal{A}}(a, b) = |\mathrm{Hom}_{\mathcal{A}}(a, b)| \quad (a, b \in \mathcal{O}b(\mathcal{A}))$$

This $\zeta_{\mathcal{A}}$ is called the *similarity matrix* of \mathcal{A} .

- (2) A weighting on \mathcal{A} is defined to be a weighting on $\zeta_{\mathcal{A}}$, similarly to a coweighting on \mathcal{A} .
- (3) \mathcal{A} is said to *have the magnitude* if $\zeta_{\mathcal{A}}$ has a weighting and a coweighting, denoting it by $\#\mathcal{A} = \#\zeta_{\mathcal{A}}$.
- (4) \mathcal{A} which has the magnitude is said to *have Möbius inversion* if $\zeta_{\mathcal{A}}$ is invertible, denoting its inverse by $\mu_{\mathcal{A}} = \zeta_{\mathcal{A}}^{-1}$.

Example 4.3.6. aaa.

4.4 The Relation of The Magnitudes of Graphs and Enriched Categories

Theorem 4.4.1. *The magnitude of a graph G defined in Definition 2.1.3 coincides with the magnitude of the $[0, \infty]$ -category corresponding to G .*

Proof. We show that a graph G is $[0, \infty]$ -category and its magnitude coincides with the magnitude of G defined in Definition 2.1.3.

First, as we see in examples, generalized metric spaces are $[0, \infty]$ -categories, which shows that G is $[0, \infty]$ -category with the metric d_G .

Second, let a monoid homomorphism $|\cdot| : [0, \infty] \rightarrow \mathbb{Q}(q)$ defined by $|x| = q^x$. Then, the similarity matrix ζ_G of the $[0, \infty]$ -category corresponding to G is given by

$$\zeta_G(a, b) = |\mathrm{Hom}_G(a, b)| = |d_G(a, b)| = q^{d_G(a, b)}.$$

This coincides with the $Z_G(q)$ defined in Definition 2.1.3.

Therefore, the magnitude of the $[0, \infty]$ -category corresponding to G coincides with the magnitude of G defined in Definition 2.1.3. \square

Theorem 4.4.2. グラフのテンソル積が *catesian product* に対応する

Appendix

A The calculation of Graph Automorphisms

Proposition A.0.1. *Let $G = K_{n,n}$. Then, $\text{Aut}(G) \approx (\mathfrak{S}_n \times \mathfrak{S}_n) \rtimes_s \mathbb{Z}_2$, where $s : \mathbb{Z}_2 \rightarrow \text{Aut}(G); 0 \mapsto \text{id}_G, 1 \mapsto \tau$ and τ is the automorphism which interchanges the two parts of $K_{n,n}$.*

Proof. Now,

$$0 \rightarrow \mathfrak{S}_n \times \mathfrak{S}_n \xrightarrow{\text{incl}} \text{Aut}(G) \xrightarrow{s} \mathbb{Z}_2 \rightarrow 0$$

is exact and this sequence splits. Thus, we have $\text{Aut}(G) \approx (\mathfrak{S}_n \times \mathfrak{S}_n) \rtimes_s \mathbb{Z}_2$. \square
