1 Introduction

Lamport's guide to L^AT_EX [1].

2 The Magnitude of Graphs

In this section, we define the magnitude of a graph G and the magnitude homology of a graph G , give some very basic examples and properties. By a *graph* we mean a finite undirected graph with no loops or multiple edges. The set of vertices of a graph G is denoted by $V(G)$, and the set of edges of G is denoted by $E(G)$. If x and y are vertices of a graph G , then the *distance* $d_G(x, y)$ between x and y is defined to be the length of a shortest edge path from x to y . If x and y lie in different components of G then $d(x, y) = \infty$.

2.1 The definition of the magnitude of Graphs

Here, we define the magnitude of a graph, which can be expressed as either a rational function over \mathbb{Q} or a formal power series over \mathbb{Z} . Write $\mathbb{Z}[q]$ for the polynomial ring over the integers in one variable q and $\mathbb{Z}[[q]]$ for the ring of formal power series over the integers in one variable q .

Definition 2.1.1. Let G be a graph. We define the G -matrix $Z_G = Z_G(q)$ over $\mathbb{Z}[q]$ whose rows and columns are indexed by the vertices of G , and whose (x, y) -entry is given by

$$Z_G(q)(x, y) = q^{d(x, y)} \quad (x, y \in V(G))$$

where by convention $q^\infty = 0$.

G -matrix is the square symmetric matrix.

Proposition 2.1.2. G -matrix is invertible.

Proof. By definition, the determinant of Z_G has constant term 1, which implies that $\det Z_G \neq 0$. \square

Definition 2.1.3. The *magnitude* of a graph G is defined to be the rational function given by

$$\#G(q) = \sum_{x, y \in V(G)} (Z_G(q))^{-1}(x, y)$$

in the rational function field $\mathbb{Q}(q)$.

Remark 2.1.4.

$$\#G(q) = \text{sum}(Z_G(q)^{-1}) = \frac{\text{sum}(\text{adj}(Z_G(q)))}{\det(Z_G(q))}$$

where adj is the adjugate matrix and sum is the sum of all entries of a matrix.

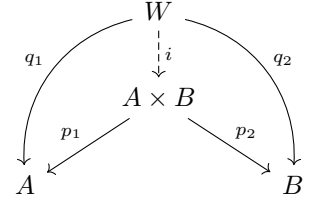

Proposition 2.1.5. $\#G(q)$ takes values in $\mathbb{Z}[[q]]$.

Proof. Let $\det Z_G(q) = 1 - qf(q)$ for some $f(q) \in \mathbb{Z}[q]$ by theorem 2.1.2. Then we have

$$\#G(q) = \frac{\text{sum}(\text{adj}(Z_G(q)))}{\det(Z_G(q))} = \text{sum}(\text{adj}(Z_G(q))) \sum_{n=0}^{\infty} q^n f(q)^n$$

Note that $qf(q)$ has no constant term and then $\sum_{n=0}^{\infty} q^n f(q)^n$ takes values in $\mathbb{Z}[[q]]$. □

Example 2.1.6. Let $G = K_3$ (complete graph with three vertices).
